Aktivita pentosového cyklu v erythrocytech otylých žen - Sliwowski A. Klin. Chor. Wewnetr. Akad. Med., Warszawa - VNITRNI LEK. 1958, 4/7 (593-598) Graphs 3

The concentration of ribose in erythrocytes of normal women rose to 94 µg./ml. erythrocytes, whereas in obese women the concentration of ribose rose to 153 µg./ml. on the average. The calculated rate of glucose utilization via the pentose cycle in erythrocytes of normal women was 5.6% and in obese women 20%. These differences are statistically significant. The data suggest that the pentose cycle enhances liposynthesis by providing reduced TPN. (II, 6)

SOURCE: Ref. zh. Vodnyy transport, Abs. 10A84

REF SOURCE: Sudostro. i morsk. sooruzh. Resp. mezhved. nauchno-tekhkn. sb., vyp. 1, 1965, 21-31

TOPIC TAGS: rudder, hydrodynamics, shipbuilding engineering, AXIAL FLOW

ABSTRACT: A single rudder exposed to the action of an axial flow on the screw-headpiece complex of an active rudder is investigated. The effect of the flow around the cap and screw in the headpiece on the hydrodynamic characteristics of the blade of the active rudder is determined, and the passing flow generated by the blade of the active rudder is investigated. Expressions are derived for the coefficient of the rudder's side force and the hydrodynamic moment relative to the forward edge of the active rudder's blade.

Title: Magnesia Binders from Local Dolomites

Original

Periodical: Kauno politechn. inst. darbai, Tr. Kaunassk. politekhn. in-ta,
1955, 3, 35-41; Lithuanian; Russian resumé

Abstract: It was found that most dolomites (D) of Lithuanian SSR are suitable
for production of caustic D. However these D have an important de-
fect, namely a narrow temperature interval of calcining (50°). An
exception is the D of Paroveysk bed the calcining interval of which
is of 150° . This D calcined at optimal temperature of 650° has the
following characteristics: content of free CaO 1.53%; and MgO 22.7%;
standard thickness of paste on mixing of $MgCl_2$ 30%; tensile strength
after one day 21.9, after 28 days 56.2 kg/cm^2 ; compression strength
after one day 154 and after 28 days 525 kg/cm^2 .

Use of hydraulic lime for production of autoclave-hardened silica ware. V. Sližys and V. Parfionovas. *Lietuvos TSR Mokslo Akad. Darbai, Ser. B* 1957, No. 3, 33-40 (in Russian; Lithuanian summary, 50). — The possibility of production of autoclave-hardened silica ware, by using hydraulic lime obtained from chalky marl of Valkininkai by 2-hr. calcining at 930-50, was investigated. It was established that silica wares prep'd. with hydraulic lime as a binder are of sufficient strength. This strength is acquired on hydrothermal hardening of articles previously compressed under 150-250 kg./sq. cm., and depends not only on hydration of dicalcium silicate and monocalcium aluminate, but also on the newly formed hydrates of Ca silicate produced by the interaction of free CaO with quartz sand. Thus, the presence of 18-27% of free CaO in the hydraulic lime used was found essential to the strength of the articles produced. It was also established that the addn. of finely dispersed clay or chalky marl sharply increases the mech. strength of raw and hardened silica ware. Thus, samples composed of 10% hydraulic lime (contg. 20.66% of free CaO and 90% sand, mixed with 10% water, compressed to 200 kg./sq. cm., and hardened for 8 hrs. under 8 atm. had a compressive strength of 148 kg./sq. cm. Similar samples, where 25% sand was replaced with a finely divided chalky marl, mixed with 12% of water and further treated as above, possessed a compressive strength of 200 kg./sq. cm. Similar results were obtained with 30% of finely divided clay. Moreover, the addn. of marl or clay enables one to use lime as rich in MgO as 10% and requires shorter autoclaving time. The increase of lime content up to 18%, stronger compression of raw articles, and higher autoclaving pressure result in an increase of compressive strength of final articles. I.V.

TITLE: Direct electron-microscopic examination of the fine structure of glass

PERIODICAL: Akademiya nauk SSSR. Doklady, v. 141, no. 3, 1961, 674-676

TEXT: Since the structure of replicas disturbs the electron-microscopic examination of glass, the authors developed a method of direct electron-microscopic glass examination. They used a JEM-5V electron microscope. Glass films were obtained from 0.2-0.5 mm thick glass laminas by grinding and polishing, or by blowing the molten glass with subsequent etching. Glass laminas were dissolved in HF until they permitted good penetrability to the electron beam. The laminas were first etched with 20%, then with 10; 4; 2; and 0.5% HF. Blown glass was etched with 4; 2; and 0.5% HF. Distinct fine structures were also obtained by etching with lye. The electron-microscopic examination showed that two-, three-, and multi-component glasses were not homogeneous. [Abstracter's note: electron

A study of some physico-mechanical... a tendency to crystallisation were not submitted to the secondary annealing. Two types of specimens were used for the investigations: cylindrical 15-20 mm diameter, 5-15 mm height; and small glass chips 1-4 mm diameter in which no stresses could be detected with a polariscope. The microhardness was determined by means of a diamond pyramid indentor; the microstrength and the brittleness criterion were calculated from the dimensions of the indentations, using the following formulae of N.K. Dertev:

$$R = 4800 \frac{P(1 + 2\mu)}{4d^2 + \ell^2} \quad (2)$$

$$T = 0.61 \left(4 + \frac{\ell^2}{d^2} \right) \left(\frac{1 - 2\mu}{1 + 2\mu} \right) \quad (3)$$

where: R - microstrength in tension, kg/mm²; T - brittleness criterion; P - indentor (load), g; ℓ - length of crack at the angles, microns; d - length of the diagonal of the indentation, microns; μ - Poisson coefficient.

According to preliminary experiments on homogeneous optical glass

Card 2/4

A study of some physico-mechanical... s/236/62/000/002/002/004
E071/E135

K-8, residual stresses have no noticeable effect on the length of cracks in the indentations unless they are of the order of 100 $\mu\text{m}/\text{cm}$; the values for some of the synthesised glasses were 10-50 $\mu\text{m}/\text{cm}$. The residual stresses in small glass chips, obtained by thermal cracking or mechanical breaking of large pieces, do not disappear although the polariscope does not show presence of stresses. It was found (using glass $\text{Na}_2\text{O} \cdot \text{CaO} \cdot 5 \text{SiO}_2$) that melting of glass during 2 and 4 hours has no practical influence on its strength characteristics, while a prolonged high temperature annealing lowers the microhardness and increases the resistance to cracking. As a rule, with increasing indenter load (50-150 g) the microhardness of glasses free from traces of crystallisation decreases by 3-8%, the microstrength decreases by 25-35%, but the brittleness criterion increases by 15-20%. Conclusions:
1) As regards their influence on increasing the microhardness, alkali earth oxides can be placed in the following order:
 $\text{BeO} > \text{CaO} > \text{MgO} > \text{SrO} > \text{BaO}$ and $\text{ZnO} > \text{CdO}$; and as regards their influence on the microstrength, in the following order:
 $\text{BeO} > \text{MgO} > \text{CaO} > \text{SrO} > \text{BaO}$ and $\text{ZnO} > \text{CdO}$.

Card 3/4

A study of some physico-mechanical ... S/236/62/000/002/002/004
EG71/E135

- 2) Alkali oxides increase the microhardness and microstrength of glasses in the following order: $\text{Li}_2\text{O} > \text{Na}_2\text{O} > \text{K}_2\text{O}$.
 - 3) Alkali oxides lower the brittleness of glasses in the following order: $\text{K}_2\text{O} > \text{Na}_2\text{O} > \text{Li}_2\text{O}$.
 - 4) Glasses of the same microhardness but with lower values of the brittleness criterion are stronger.
 - 5) In the ternary system $\text{Na}_2\text{O}-\text{CaO}-\text{SiO}_2$ the microhardness depends mainly on the proportion of calcium oxide.
- There are 8 figures and 6 tables.

TITLE: A direct electronmicroscopic investigation of the fine
structure of di-, tri- and multi-component silicate
glasses

PERIODICAL: Trudy Akademii nauk Litovskoy SSR, Seriya B, 2(29),
1962, 95-108.

TEXT: In view of the scarcity and some uncertainties of the results obtained in published investigations, a study of the fine structure of transparent glasses was undertaken, on the following types of glass: $Na_2O \cdot 5 SiO_2$, $R_2O \cdot xR_2O \cdot 5 SiO_2$ (where $R_2O = Li_2O$, Na_2O , K_2O ; $R_2O = BeO$, MgO , CaO , ZnO , SrO , CdO , BaO , PbO ; $x = 0.5, 1.0, 1.5, 2.0, 2.5$ and 3.0) as well as on some multi-component glasses - ordinary sheet glass, glass electrodes etc. The development of a suitable method was done using glass of composition $Na_2O \cdot CdO \cdot 5 SiO_2$. The electron microscope used had a resolving power of about $8-10 \text{ \AA}$ (magnification 50-100 thousand). Initially, carbon replicas with a preliminary shading of a fresh

Card 1/3

A direct electronmicroscopic ...

S/236/62/000/002/003/004
E071/E135

glass fracture at an angle of 15-20° with platinum or tungsten oxide were used. These replicas, however, showed their own structure and not that of the glass. Subsequently carbon-platinum replicas were made, applying the method of D.E. Bradley, by spraying a thin platinum-carbon film at an angle of 45° to the surface of the glass. Since this method is very laborious and the replicas can to some extent distort the actual glass structure, a direct method of preparation of glass films for studying the structure was developed. Initially, this consisted in etching thin, polished glass plates (0.2-0.5 mm thick); later blown glass films were used which were subsequently etched in hydrofluoric acid or mixtures of hydrofluoric with another mineral acid, until a necessary thin film was obtained. The experimental procedure is described in some detail. The structure observed directly on a thus prepared specimen of Na₂O·CdO·5 SiO₂ glass was identical with that observed on the replica prepared by the Bradley method. The specimens prepared by etching showed not only the surface structure of glass, but in some cases the distribution of micrononuniformities in the whole thickness of the glass film. Therefore this method of investigation was used in further studies. It was established

Card 2/3

A direct electronmicroscopic ...

S/236/62/000/002/003/004
E071/E135

that none of the glasses investigated were homogeneous; they consist of a skeleton rich in silica and a multiplicity of micro-dendrites which depend on the chemical composition of glass as well as on its thermal history and technological factors. The majority of the glasses investigated had microdendrites of an order of 40-100 Å.

There are 4 figures and 1 table.

TITLE: The selection of composition for the production of foamed glass

SOURCE: Akademiya nauk Litovskoy SSR. Trudy. Seriya B, no. 4, 1962, 71-76

TEXT: Sheet window glass, bottle glass and laboratory-prepared $\text{SiO}_2\text{-Al}_2\text{O}_3\text{-Fe}_2\text{O}_3\text{-CaO-MgO-Na}_2\text{O-K}_2\text{O}$ glasses were investigated in an effort to reduce the required foaming temperature and therefore lower the costs of this processs. The alkali contents of the laboratory glasses were 15 - 17% and 19 - 20%. The specimens were foamed at 620 - 870°C, using 2% (by weight) of north-western Lithuanian limestone from the "Karpenay" deposit as the foaming agent, and their weights by volume were determined as a function of the foaming temperature. It was found that the latter property was considerably raised by small amounts of Al_2O_3 , and was lowered

Card 1/2

The selection of ...

S/236/62/000/004/003/009
D204/D307

by Fe_2O_3 and Na_2O , although large additions of the alkali made the glass hygroscopic. Thus the cheap, Fe-containing bottle glass (from the "Alyalsotas" factory) could be foamed at lower temperatures than the sheet window glass, i.e. at $730 - 830^\circ\text{C}$ with limestone or dolomite, and at $730 - 800^\circ\text{C}$ with coke. At higher temperatures the pores were larger and more uneven. The foaming range could be increased by the addition of CaO and MgO . There are 3 tables.

ties and on the structures of silicate glasses.¹⁵ Mechanical properties

SOURCE: AN LitSSR. Trudy. Seriya B. Fiziko-matematicheskiye, khimiches-
kiye, geologicheskiye i tekhnicheskiye nauki, no.2, 1965, 97-109

TOPIC TAGS: silicate glass, glass property, magnesium oxide, calcium
oxide, zinc oxide, inorganic oxide

ABSTRACT: A study was made of the effects of high temperature heat
treatment of window glass and of glasses with a molar ratio of Na₂O-RO-
5SiO₂, where RO represents beryllium oxide, magnesium oxide, calcium
oxide, strontium oxide, cadmium oxide, or barium oxide. These effects
were measured in terms of microhardness, micro-breaking strength, bending
strength, and elastic state. The samples were subjected to heat treat-
ment at 550, 650, 800, and 1200°C and were held at these temperatures for
periods of 3, 6, 12, 50, 100, and 500 hours. Experimental results are

Card 1/2

L 11048-66

ACC NR: AP6000671

presented in tabular form. It was found that, while the microhardness within limits of the experimental error is practically independent of heat treatment, the micro-breaking strength and the bending strength for glasses without a tendency toward crystallization increase insignificantly as a function of the heat treatment, while for glasses with a tendency toward crystallization they decrease. It was shown that microbrittleness, as a function of the heat treatment, increases to a greater degree the greater the tendency of the glass toward crystallization. The Poisson coefficient of the glasses, within the limits of experimental error, does not vary as a function of the heat treatment, while the Young modulus and the shear modulus increase insignificantly. In general it is concluded that it is impossible to increase the strength of glasses by prolonged heat treatment. Orig. Art. has: 6 tables.

kiye, geologicheskiye i tekhnicheskiye nauki, no.2, 1965, 111-124

TOPIC TAGS: silicate glass, glass property, solid mechanical property,
zinc oxide, barium oxide, magnesium oxide, inorganic oxide

ABSTRACT: A study was made of the electrical properties of three-compo-
nent sodium silicate glasses containing beryllium oxide, magnesium oxide,
zinc oxide, strontium oxide, cadmium oxide, and barium oxide, as well as
ordinary window glass. Before measurement of electrical properties, the
glass was subjected to heat treatment at 550, 650, and 800°C for 500
hours. For purposes of comparison, identical measurements were also made
on glasses which had not been subjected to heat treatment. To exclude
the effect of atmospheric moisture on the values of the electrical prop-
erties, the measurements were made at elevated temperatures. The first

Card 1/2

L 11047-66

. ACC NR: AP6000672

determination of electrical properties was made at 350°C, with subsequent measurements at 300, 250, 200, 150, and, when necessary, at 130 and 110°C. Measurements were made of the specific resistance, the dielectric losses, and the dielectric constant. Experimental results, exhibited in tabular form, show that with an increase in temperature of heat treatment from room temperature to the transformation temperature there is an increase in the specific resistance and a decrease in the dielectric losses and in the dielectric constant. With an increase of heat treatment temperature above the transformation temperature, there is a decrease in the specific resistance and an increase in the dielectric losses and the dielectric constant. TITLE: The "take" of foreign bodies in radiation sickness

PERIODICAL: Voyenno-meditsinskiy zhurnal, no. 7, 1960, 60-65

TEXT: The aim of the study was to determine the effects of radia-
tion sickness on the "take" of foreign bodies (shrapnel, bullets)
in the tissues. The combined action of the radiation factor and
foreign body injuries was observed in rabbits. All rabbits were
treated with antibiotics (penicillin) for 3 days after injury. The
tests were arranged in the following series: 1) sterile and 2)
staphylococcus-infected foreign bodies introduced into non-irradia-
ted animals; 3) sterile and 4) infected foreign bodies into gener-
ally irradiated animals (1,000 r); 5) sterile foreign bodies into
animals irradiated with Au¹⁹⁸; 6) gunshot wounding of rabbits gen-

X

Card 1/2

erally irradiated with 500-1,000 r. The results showed that the foreign bodies and resultant tissue lesions had no appreciable effect on the course of radiation sickness, except for cases where the tissue was considerably destroyed or with purulent necrotic complication of the wound process. Mild and medium radiation sickness from general irradiation did not inhibit encapsulation of the foreign bodies, whereas severe radiation sickness inhibited it greatly. Radiation sickness from radioactive substances introduced directly into the tissues and organs inhibited the plastic process. Penicillin reduced the number of postvulnral complications, but streptomycin and other antibiotics could also be used instead. The authors conclude that surgical treatment for deep-lying foreign bodies, not removed during primary surgery, in persons affected by ionizing radiation should be governed simply by the clinical symptoms of vulnerability. S.S. Sokolov, N.I. Blinov, V.G. Vaynshteyn, A.S. Rovnov, B.M. Khromov, A.D. Yarushevich and I.A. Meshcheryakov are listed as Soviet scientists who have studied combinations of radiation sickness with traumatic injuries.

Machines and Devices for Mining in Frozen Ground in
Winter (Mashiny i prisposobleniya dlya razrabotki
merzlykh gruntov v zimniy period)

PERIODICAL:

Mekhanizatsiya i avtomatizatsiya proizvodstva, 1959,
Nr 2, pp 15-18 (USSR)

ABSTRACT:

The article deals with mining problems in open-cut mines in winter, when the multi-bucket excavators cannot work satisfactorily (frequent break-downs), because of the frozen ground. The authors recommend the following methods: 1) the warming-up and defrosting of the mine benchings by means of electrodes driven into the ground vertically or horizontally. This method is expensive and may be used only in small open-cut mines; 2) the preliminary loosening-up of the frozen ground using SE-3 excavators; 3) the blowing-up of the frozen ground. Electric drills of the EBR-19D type are used for the boring of blast holes.

Card 1/2

SOV/118-59-2-4/26

Machines and Devices for Mining in Frozen Ground in Winter

The firing is carried out in series of 12. This method has been successfully used by Metrostroy, "Elektrostal'-stroy", "Soyuzekskavatsiya" and during the building of the Moskovskiy energeticheskiy institut (the Moscow Institute of Power Engineering); 4) the use of drag-line excavators mounted on S-80 tractors (the most economical method); and 5) the use of diesel hammers mounted on S-80 tractors, E-505 excavators, tractor loaders and special framings. The application of diesel hammers mounted on D-157 bulldozers has been recommended by engineer I.N. Sokolov and was used while building the Institute of Power Engineering in Moscow. There are 4 diagrams, 1 photograph, and 1 table.

TITLE: Determination of the thermal utilization factor for multizone circular cells

SOURCE: Inzhenerno-fizicheskiy zhurnal, no. 1, 1964, 80-88

TOPIC TAGS: thermal utilization factor, multizone circular cell, thermal neutron, nuclear reactor, neutron beam, albedo, transmission function, multizone cell, thermal utilization

ABSTRACT: Formulas are derived for calculating the thermal utilization factor (of neutrons) in a multizone circular cell by the albedo and the transmission functions of each zone. Ways are examined of finding the albedo and the transmission functions for a cylindrical, circular, and external zone, assuming isotropic angular distribution at the boundaries of neutrons traveling in one direction. The simplified method proposed, based on three variables, allows calculations to be made with sufficient accuracy without computers. Knowledge of the albedo and transmission functions may be used to calculate the effectiveness of multilayer circular control rods and other problems as well. Orig. art. has 22 numbered formulas.
